Title : Two Fatal Cases of Poisoning by Organic Solvents.

Orig Pub : Arhiv. hig. rada i toksikol., 1956, 7, No 2, 94-96

Abstract : The fatal poisoning of two workers, engaged in the painting of water pipes in a closed room of 24 m^3 capacity, is described. Used in the paint was a solution of bitumen (73%) in a mixture of benzene (21.6%) and benzol (5.4%). The area of the painted surface was 7.5m^2. The circumstances of the event and the autopsy results showed that poisoning by solvent vapors was the cause of death.

BUDAKHOVA, L.M.

AUTHORS Budahova L.M., Volodarskaya R.S., 32-7-8/49
TITLE The Trilonometrical Determination of Magnesium in Aluminum Alloys. (Trilonometricheskoye opredeleniye magniya v alyuminiyevykh splavakh -Russian)
PERIODICAL Zavodskaya Laboratoriya, 1957, Vol 23, Nr 7, pp 797-797 (U.S.S.R.)

ABSTRACT This determination can be carried out by trilon-titration after the removal of disturbing components. On this occasion zinc and aluminum are separated by alkalis, whereas copper, nickel, manganese, and iron are separated by sodium-diethyldithiocarbonate. If the alloy contains 0,5% magnesium, no nickel, and if its manganese content is less than 0,5% a buffer mixture may be used instead of the former, and it is possible to separate the magnesium from the elements disturbing titration. Carrying out of the analysis is described. There is 1 figure.

Title : Some Physical Properties of the Takyry

Orig Pub : Takyry Zap. Turkmenii i puti ikh s.-kh. osvoyeniya, Moskva, Akad Nauk SSSR, 1956, 489-512.

Abstract : This is an examination of the physical properties of the takyry of the Kopet-Dagh mountain plain and the lower reaches of the Amu-Dar'ya. The volumetric weight -- 1.4 -- of the upper part of the crust is much lower than that of the lower part of the crust which, to a depth of 1.65 cm., looks like a dwarf alluvial /illyuvial'nyy/ horizon. The total, including non-capillary, porosity of the upper part of the crust reaches 16%, and ~ 6% in the lower part; the maximal hygroscopic moisture and the withering coefficient

are, correspondingly, 4.9% and 5.2%. When the takyry of the mountain plain are wet and the temperatures low, the speed of filtration is very slight -- 0.000003 cm./second, or 1 m^3/hectare per hour. When the weather is warm the speed of absorption increases more than 1000%, reaching 14 m^3/hectare per hour. The poor filtration qualities of the takyry derive from the properties of the crust and of the rocks from which the soil is formed -- the amount of clay which they contain, their stratification. Breaking up the surface horizons of the takyry to a depth of 25 cm. improves their filtration properties only for two hours. A longer-lasting effect can be attained by combining plantage plowing /plantazhnaya vspyshka - sic/ with application of organic fertilizers or sand; this method raises the speed of filtration to 50-80 m^3/hectare per hour. The field moisture capacity of the

Title : Elements of the Moisture Regime of the Takyry

Orig Pub : Takyry Zap. Turkmenii i puti ikh s.-kh. osvoyeniya, Moskva, Akad Nauk SSSR, 1956, 513-521.

Abstract : In the takyry moisture travels exclusively in capillarily suspended solutions. Ground waters ordinarily have no effect on the water regime of the takyry. One characteristic of the water regime of the takyry, and of the takyr soils, is the extreme dessication of their upper horizons, up to hygroscopic moisture, /?/, in the summer period. The drying up of the crust horizon of the takyry can occur also during the winter (in the intervals between deposits of precipitation); this is due to certain

TITLE: Contemporary Vertical Movements of the Western Shores of Bering Sea (Sovremennyye vertikal'nyye dvizheniya zapadnykh beregov Beringova morya)

PERIODICAL: Tr. Okeanogr. komis. AN SSSR, 1956, Nr 1, pp 65-72

ABSTRACT: The western shore of the Bering Sea may be divided into a number of parts according to the character of their contemporary vertical movements. Along the southwestern and western shore of the Anadir Bay, the southern part of the Koryak shore and the western part of eastern Kamchatka an uplifting may be observed at this time. In the portion of the shore from Ushakov cove northward to the Dezhnev cove then

Contemporary Vertical Movements (Cont.)

southward and along the shore of the Olyutorskiy Cape a slow relative subsidence is taking place. The regions of uplift and subsidence are separated by a zone of relative stability. The following factors bear witness to the contemporary uplift: 1) increase in the absolute height of shore ridges as their distance from the shore increases, that is, as they pass from the younger to the older ones; 2) signs of drying off in those parts of the lagoon bottoms which lie behind natural dams (the dry portions are lifted above the water level in the lagoons to a height of 0.3 m to 0.5 m and show no signs of being submerged; 3) presence of submarine abrasional terraces in the bedrocks of the submarine shore slopes; 4) diminishing of abrasional steps; 5) cutting of river outlets into the contemporary terrace. The signs of present subsidence are: 1) diminution of the absolute height of ancient shore ridges as their distance from the contemporary shore line increases; 2) character of the submerged off-shore slope: presence of very wide abrasional terraces in the bedrock, stretching out to a considerable depth and showing no distinct

Contemporary Vertical Movements (Cont.)

curvature in their profile; 3) wide distribution of active abrasional steps; 4) presence of perched outlets which were formed because the time of incision lagged behind the time of the shore recession, due to the intensification of the process. For signs of the stable state of the shore we take: 1) approximately equal height of the ancient shore ridges and the contemporary storm ridges; 2) wide distribution of well developed submerged abrasional terraces formed in the bedrock and in the Quaternary strata. The article includes a schematic map of the western shore of the Bering Sea, showing the character of vertical movements in various locations and the profiles of the leveled contemporary marine accumulations.

TITLE: Recent Vertical Motion of the Shores of the Far East Seas (Sovremennyye vertikal'nyye dvizheniya beregov dal'nevostochnykh morey).

PERIODICAL: Doklady AN SSSR, 1957, Vol. 116, Nr 6, pp. 1005-1008 (USSR).

ABSTRACT: In literature there often appear data about the kind of the recent and not long ago motions of the shores in the Far East and Northeast of the USSR. Frequently, the data about the velocity and direction of these shiftings contradict each other, coarsely. Such an estimation apparently has its cause in a) different conceptions of the mechanism of formation of the shore-relief-forms; b) imperfection of the method of investigation and c) an indistinct limitation of the characteristics of not long ago and vertical notions. These latter are defined here. The authors used a uniform theory of method which is in use in the Laboratory for Bottom of Sea- and Shore Relief (of the institute, see below: "association"). Thus, comparable results were rendered possible. Here the theory of method is described shortly. The shores of the Far East Seas are divided according to the kind of their recent

vertical motions into a number of sections: some are sinking, other are rising; finally there are relative steady sections. The clearest symptoms of the sinking were stated: in the Eastern and Northern part of the Chukot Peninsula ("Chukotskiy poluostrov"), on the Northeastern shore of the Korayken Highland ("Korayskoye nagor'ye") in some sections of the Eastern- and Western shore of Kamchatka, in the surroundings of the town Okhotsk, and at the Northeastern shore of Sakhalin. The raising-zones are: Western shore of the Anadyr Bay, individual sections of the Northeastern- and Eastern Kamchatka, farther the shore of Southern Sakhalin and the Sea Province. The characteristics for the above-mentioned classification are given. In connection with post-glacial transgression all shores of the Far East Seas have an ingression appearance. But that does not mean a recent shore-sinking, because at the raising shores the eustatic raisung of the level was not compensated by tectonic motions. Therefore the observed raising is not relative, but absolute. Low sinking or stability of individual shore sections are to be estimated relatively. They form an algebraic term of a sum of the eustatic raising of the world ocean during the late glacial period and tectonic motions of the continent. No sections with high velocities

Recent Vertical Motion of the Shores of the Far East Seas.

of motion have been observed. By the differences of the height of the old shore quays the authors conclude that the velocity of the relative sinking of the Western-Kamchatka shore exceed that one of the Eastern part of the Chukot-Peninsula by the 3 - to 4 -fold. The definition of absolute velocities just is impossible because of the deficiency of proofs.

AUTHOR: Budanov V.I.

TITLE: Some Ways of Analyzing Sea Bays

PERIODICAL: Izvestiya Akademii nauk SSSR, Seriya Geograficheskaya, 1959, Nr 2, pp 102-104 (USSR)

ABSTRACT: This is an analysis of the structure, genesis and present state of a tongue of land, which belongs to the Koryak littoral of the Bering Sea, and secludes a bay from the ocean. The analysis has been carried out under the aspect of the dynamic forces of the sea, which have shaped and are still shaping this strip of land, giving it a petrographic structure of its own. There is 1 map and 1 Soviet reference.
